Abstract

It is generally accepted within psychology and among trans health providers that transgender people who transition do so because they have a gender identity that is incongruent with their birth-assigned sex, and distinct from their sexual orientation. In contradiction to this standard model, the theory of autogynephilia posits that transgender women’s female gender identities and transitions are merely a by-product of their sexual orientations. While subsequent research has yielded numerous lines of evidence that, taken together, disprove the theory, autogynephilia is still often touted by anti-transgender groups, including trans-exclusionary feminists. Here, I provide an updated overview of the scientific case against autogynephilia. Following that, I will forward an alternative ‘embodiment fantasies’ model that explains all the available findings better than autogynephilia theory, and which is more consistent with contemporary thinking regarding gender and sexual diversity. I will also demonstrate how autogynephilia theory relies on essentialist, heteronormative, and male-centric presumptions about women and LGBTQ+ people, and as such, it is inconsistent with basic tenets of feminism.

Keywords

autoandrophilia, autogynephilia, sexual fantasies, transgender, transsexual

Introduction

Over the last decade, psychologist Ray Blanchard's autogynephilia theory has been increasingly cited within trans-exclusionary radical feminism. The concept appears to have first entered trans-exclusionary radical feminist (TERF) discourses through Sheila Jeffreys's writings (Jeffreys, 2005, 2014). It has since become a recurring talking point on 'gender critical' websites such as 4thwavenow, r/GenderCritical (a subsection of the website Reddit), Mumsnet, and others, where it is usually invoked to insinuate that trans women are merely 'sexually deviant men.' In such settings, autogynephilia is typically presented as though it were well-established scientific dogma, when in reality the theory has never been widely accepted within sexology and psychology, and numerous follow up studies have disproven its primary claims. Furthermore, trans-exclusionary feminists' uncritical embrace of autogynephilia contradicts the long history of feminist scholarship critiquing the ways in which scientific research and theories are often overly reductionist, and riddled with androcentric and heteronormative biases (reviewed in Crasnow et al., 2018; Fehr, 2004).

In this paper, I will review the scientific case against autogynephilia theory, and provide an alternate model that is far more consistent with all the available evidence and contemporary thinking in the fields of sexology and psychology. Additionally, I will demonstrate how autogynephilia theory is steeped in gender-essentialist and male-centric views of gender and sexuality, and thus is inconsistent with feminist thought.

Autogynephilia: historical context and the scientific evidence

Today, it is widely accepted that gender identity, gender expression, sexual orientation, and physical sex characteristics may vary from one another within any given individual, and that gender dysphoria (incongruence between one's gender identity and assigned sex/gender) may first arise during childhood, adolescence, or adulthood (American Psychological Association, 2015; Coleman et al., 2011; Hidalgo et al., 2013). There has also been a growing recognition that many sexual fantasies and patterns of arousal that have historically been categorized as 'sexual deviations' or 'paraphilias' (ie, pathological sexual interests) are not especially rare, nor are they inherently unhealthy (Joyal et al., 2015; Moser and Kleinplatz, 2006). As a result, researchers have gradually moved away from viewing solitary and consensual expressions of sexuality as manifestations of psychopathology (Giambi, 2015). For all of these reasons, there is now a general consensus amongst contemporary trans health professionals that transgender people are diverse with regards to their gender expressions, sexual orientations, sexual fantasies, and life trajectories (just as cisgender people also vary in these aspects of their lives).

But this was not always the case. For most of the twentieth century, research into these matters was steeped in gender essentialism and reductionism. Women and men were believed to be naturally distinct from one another in their genders and sexualities, and individuals who did not neatly fit into this strict binary (ie, LGBTQ+ people) were categorized into subtypes based upon superficial similarities and presumed underlying pathologies. During this time period, assigned male at birth (AMAB) transgender-spectrum people were often classified into one of two subgroups: transsexuals or transvestites. *Transsexuals* – those who socially and/or physically transition; more commonly called *trans women* and *trans men* today – were

simplistically imagined as ‘males with feminised brains’ and ‘females with masculinised brains,’ respectively. Given this conceptualisation, researchers presumed that trans women would not only identify as women, but should also be feminine in gender expression throughout their lives and exclusively sexually oriented toward men; this archetype was sometimes called the ‘classical transsexual.’ Notably, researchers who subscribed to this ‘sexual inversion’ narrative often described gay men in a similar fashion (ie, feminised brain, therefore feminine in gender expression and exclusively attracted to men) and believed that homosexuality and transsexuality merely represent different outcomes for the same ‘type’ of person. In contrast, *transvestites* (often called *crossdressers* today) were envisioned as otherwise ‘normal’ (read: heterosexual and masculine) men, except for the fact that they (1) occasionally wore female-typical clothing, usually in secret, and (2) sometimes experienced sexual arousal associated with dressing femininely and/or imagining themselves as having sex characteristics associated with women (eg, breasts, vulva). For reasons that will become clear, I will collectively refer to these latter sexual experiences as *female/feminine embodiment fantasies (FEFs)* (Serano, 2010, 2016).

Throughout the 1970s and 1980s, this transsexual/transvestite dichotomy was called into question, as increasing numbers of trans women did not fit the ‘classical transsexual’ archetype, either because they were not outwardly feminine during childhood, and/or did not experience gender dysphoria until adolescence or adulthood, and/or were asexual, bisexual, or lesbian in sexual orientation, and/or had a previous history of identifying as crossdressers and/or experiencing FEFs. Here, I will collectively refer to such individuals as ‘non-classical’ trans women, but not because I believe them to be distinct from, or less authentic than, their ‘classical’ counterparts. Rather, they are ‘non-classical’ in the sense that they challenged the ‘classical transsexual’ standard that most researchers and medical gatekeepers enforced at the time. Today, all of these differing outcomes (‘classical’ and ‘non-classical’ alike) are readily explained in terms of gender and sexual diversity, as I outlined earlier.

But in 1989, as practitioners were still trying to make sense of these exceptions to the ‘classical transsexual’ and ‘transvestite’ categories, Blanchard forwarded a new theory of transgender taxonomy and aetiology: autogynephilia (Blanchard, 1989a, 1989b). The theory proposed that there were two fundamentally different types of trans women, each characterized by different ‘erotic anomalies’ (Blanchard, 1989a, p. 322). According to Blanchard, ‘homosexual transsexuals’ are trans women who fit the ‘classical transsexual’ archetype. The label suggests that Blanchard imagined these individuals as akin to feminine gay men, and other proponents of the theory, such as J. Michael Bailey, have suggested that they transition in order to attract heterosexual men (Bailey, 2003, p. 146). Blanchard grouped asexual, bisexual, and lesbian (ie, ‘non-classical’) trans women, along with male crossdressers, under the label ‘autogynephiles,’ on the basis that (according to his theory) they were all primarily motivated by ‘autogynephilia’ (literally ‘love of oneself as a woman’). While some people today inappropriately use the term autogynephilia in a manner similar to how I use FEFs – ie, to refer to a particular type of sexual fantasy or pattern of arousal that some people happen to experience – Blanchard conceptualised autogynephilia very differently. Blanchard insisted that autogynephilia was a paraphilia that arises as a result of a ‘misdirected heterosexual sex drive’. That is, rather than being exclusively attracted to women (as most AMAB individuals are), something goes ‘awry’ in

‘autogynephiles’ (Blanchard refers to this as an ‘erotic target location error’ – see Serano, 2010). As a result, they become primarily attracted to the thought or image of *themselves* as women. Blanchard also claimed that autogynephilia was both a sexual orientation that competes with attraction to other people, and that it is the cause of any gender dysphoria and desire to transition experienced by ‘non-classical’ trans women (reviewed in Serano, 2010).

In other words, autogynephilia is not simply a theory positing the existence of FEFs. Researchers were already well aware of this phenomenon, having previously called it by various names (eg, automonosexualism, transvestic fetishism, cross-gender fetishism). Rather, what makes autogynephilia unique is that it asserts that there are two fundamentally different types of trans women, each having a distinct sexual cause for their transsexuality (ie, either homosexuality, or autogynephilia). Thus, the theory should be judged, not by whether or not FEFs exist, but rather by whether its taxonomical and aetiological claims hold true. Or as Bailey put it, classifying trans women into distinct types ‘diagnostically makes sense only if the different types have fundamentally different causes. Otherwise, why not distinguish “tall,” “medium-sized,” and “short” transsexuals, or “blonde” and “brunette” subtypes?’ (Bailey, 2003, p. 162).

Blanchard elaborated on autogynephilia theory over a series of papers published between 1989 and 1993. This work received little attention at first, until the early 2000s, when it was promoted by Anne Lawrence and in Bailey’s pop-science book *The Man Who Would Be Queen*, at which point it came under intense scrutiny (Serano, 2020). Amongst the most prevalent objections to the theory were: (1) a general sense that trans women are fairly diverse and do not neatly fall into two discrete subtypes; (2) Blanchard’s own research showed that significant numbers of ‘autogynephilic transsexuals’ (eg, trans woman attracted to women) did not experience FEFs, while significant numbers of ‘homosexual transsexuals’ (ie, trans women attracted to men) did; (3) Blanchard’s studies also showed that many (if not most) ‘non-classical’ trans women report experiencing gender dysphoria or a desire to be female before they ever experienced FEFs, therefore FEFs could not possibly be causative of gender dysphoria; (4) both ‘non-classical’ trans women and male crossdressers often report a sharp decline (and sometimes complete absence) in FEFs over time, indicating that such fantasies are not central to these individuals’ identities or sexualities; (5) Blanchard and others often dismissed all the aforementioned exceptions to the theory as being due to lying or misreporting on the part of ‘autogynephiles,’ which essentially rendered the theory unfalsifiable (and therefore unscientific); (6) Blanchard did not use any controls in his experiments – eg, he never administered his autogynephilia-related surveys to cisgender women; (7) Blanchard’s original rationale for the theory relied heavily on the presumption that ‘non-classical’ trans men did not exist, but it has since become clear that they are actually quite common. All these lines of reasoning are discussed in greater detail in critical reviews by Moser (2010) and Serano (2010). Thus, even without any follow-up studies, it appeared that Blanchard’s proposed taxonomy (‘homosexual’ versus ‘autogynephilic’) and aetiology (that FEFs are the cause of transsexuality in ‘non-classical’ trans women) were not supported by his own evidence.

In subsequent years, several independent research groups have tested autogynephilia theory, and their results further disprove its taxonomical and aetiological claims. For starters, every single follow up study has shown that, while the correlations that Blanchard and other researchers prior to him described generally hold true (ie, that FEFs are more common in ‘non-classical’ trans women than ‘classical’ ones), counter to Blanchard’s theory there are always substantial numbers of ‘classical’ trans women who report experiencing FEFs and ‘non-classical’ trans women who report never experiencing them (Nuttbrock et al., 2011a; Smith et al., 2005; Veale et al., 2008). These studies also challenge several additional claims necessary for autogynephilia theory to be substantiated, such as the idea that FEFs compete with sexual attraction toward other people, that asexual trans women are predominantly ‘autogynephilic,’ and that bisexual trans women are merely ‘pseudobisexuals’ (Nuttbrock et al., 2011a; Veale et al., 2008).

A longstanding critique of Blanchard’s theory had been that his subtypes were not empirically derived, but rather stemmed from his initial grouping of individuals based on their sexual orientation, thus ‘begging the question’ that trans women fall into subtypes based on sexual orientation. In contrast to this approach, Veale (2014) performed taxometric analyses on her subjects’ responses to questions regarding sexual orientation, FEFs, and other aspects of sexuality, and found that the results were dimensional rather than categorical (ie, trans women fell along a spectrum rather than into distinct subtypes). In an earlier study using the same dataset, Veale et al. (2008) found that when trans women were grouped according to their experiences with FEFs, they did not differ significantly on measures of sexual orientation.

The possibility that factors other than sexual orientation may be responsible for FEFs is further supported by Nuttbrock et al. (2011a, 2011b), who found that FEFs varied considerably among trans women depending upon age and race (with the highest levels observed in older and white subjects), and that these outcomes were mediated by a history of dressing femininely in private. This finding strongly supports alternative theories that have posited that FEFs arise from, or are exacerbated by, social factors such as secretive crossdressing and/or having to hide or repress female/feminine inclinations (Serano, 2007, 2016; Veale et al., 2010); I will discuss such theories more in the following section.

As previously mentioned, Blanchard never used any cisgender controls in his studies, presumably because he assumed that FEFs were unique to trans female/feminine-spectrum people. Two research groups have since administered autogynephilia scales (similar or nearly identical to Blanchard’s) to cisgender women. Moser (2009) found that 93% of his cisgender female subjects had experienced FEFs in some capacity, with 28% experiencing them frequently. Veale et al. (2008) also found that cisgender women frequently report FEFs, with 52% experiencing them at levels comparable to Blanchard’s ‘autogynephilic’ group (see also Moser, 2010). When roughly 65% of cisgender women respond affirmatively to questions like ‘I have been erotically aroused by contemplating myself in the nude,’ or ‘I have been erotically aroused by contemplating myself wearing lingerie, underwear, or foundation garments’ (Moser, 2009), it seems both illogical and needlessly stigmatising to single out trans women as supposedly being ‘autogynephiles’ for having similar erotic experiences (unless, of course, the

label is primarily intended to pathologise trans women's sexualities even when they are female-typical).

In addition to cisgender women experiencing FEFs, subsequent studies have shown that many cisgender people experience cross-sex/gender sexual fantasies as well. In a recent study of 4,175 Americans' sexual fantasies, Lehmillier (2018) found that nearly a third of his subjects reported having sexual fantasies that involved being the 'other sex', and a quarter had fantasised about crossdressing. Blanchard has insisted that the counterpart to FEFs – sometimes called 'autoandrophilia,' but which I will refer to as *male/masculine embodiment fantasies (MEFs)* – does not exist (Cameron, 2013), but Lehmillier found that 11% of the women in his study had experienced such fantasies. In a separate study of women's sexual fantasies, Dubberley (2013) devotes an entire chapter to fantasies wherein her subjects imagined themselves possessing a penis and/or being a man, and there is plenty of additional anecdotal evidence (much of it online) detailing cisgender women (as well as transgender men) experiencing MEFs (Serano, 2016, and references therein).

Taking all this together, two things seem clear. First, *embodiment fantasies* (ie, sexual arousal in response to one's real or imagined body and/or expressions of gender) seem to be fairly common and exist in a variety of permutations. (In the following section, I will discuss why they may occur more frequently or intensely in certain subpopulations.) Thus, it would be disingenuous to assert or insinuate that they are a trans female/feminine-specific phenomenon (as autogynophilia theory does). Second, the notion that FEFs have the potential to cause transsexuality is specious and not supported by the evidence (Serano, 2010, 2020). After all, almost a third of Lehmillier's subjects experienced cross-sex/gender sexual fantasies (Lehmillier, 2018, p. 66), yet the vast majority of these people will never develop gender dysphoria or desire to transition. Furthermore, most 'non-classical' trans women either never experience FEFs, or experience FEFs only *after* they have experienced gender dysphoria, thus ruling out the possibility that FEFs caused them to become transgender (Serano, 2010). The most reasonable conclusion is that gender dysphoria develops independently in a small percentage of AMAB people, and a subset of those individuals (along with a subset of cisgender women and men) will subsequently develop FEFs for other reasons, which I will explore in the next section.

To summarise, numerous independent lines of research have shown that autogynophilia theory's major tenets – its taxonomy and aetiological claims – are false. Therefore, the concept of autogynophilia must be rejected. Admittedly, a few researchers still vociferously promote the theory, most notably Lawrence and Bailey, whose reviews and research (along with Blanchard's) account for almost all of the unwaveringly pro-autogynophilia academic literature; elsewhere, I refute many of their attempts to handwave away the counter-evidence I have presented here (Serano, 2010, 2020). Others researchers still tacitly support autogynophilia (by citing the theory, or portraying it as a 'controversial yet viable' model) perhaps due to their unfamiliarity with the research that I have reviewed here, out of respect for Blanchard's and Bailey's stature within the field, and/or because they view the theory as consistent with other beliefs or biases that they hold (detailed in the final section). Finally, some researchers have taken to using the term 'autogynophilia' as shorthand to describe FEFs; this should be avoided, as 'autogynophilia'

inaccurately portrays these fantasies as paraphilic, trans female/feminine-specific, a sexual orientation unto itself, and the cause of gender dysphoria in trans women who experience them.

Embodiment fantasies, and transgender, queer, and female subjectivities

Thus far, we have reviewed the scientific case against autogynephilia. But if we step back and consider other fields of inquiry (eg, phenomenology, sociology, gender studies), the theory appears even more suspect. Perhaps its most glaring omission is that autogynephilia entirely ignores embodiment – the well-accepted notion in philosophy and cognitive studies that our thoughts, perceptions, and desires do not happen in a vacuum, but rather occur within, and are shaped by, our bodies.

Virtually all sexual fantasies and activities involve bodies – not just the bodies of our real or imagined partners, but our own bodies as well. While sexual fantasies are not limited to bodies (they may also involve certain settings, situations, positions, behaviors, other objects, and even intricate narratives), they do often feature our own bodies interacting in various ways with other people’s bodies (Bettcher, 2014; Dubberley, 2013; Lehmiller, 2018; Leitenberg and Henning, 1995). Sometimes our attention might be focused more on another person’s body: appreciating their physical attributes; imagining things we wish to do to, or with, their body. Other times we might be focused more on our own body: imagining other people finding us desirable; imagining them doing things to, or with, our body, and the sensations we might physically experience as a result. Often, both of these aspects (along with other elements) will be in play simultaneously during our sexual fantasies and experiences. But in other cases, one aspect may be more prevalent or even predominate. And just as we may sometimes fantasise about imaginary sex partners, it is not uncommon for individuals to imagine being entirely different people in their fantasies, or ‘having a different body shape, genital appearance, or personality’ (Lehmiller, 2018, p. xviii).

This is why I favour ‘embodiment fantasies’ as a non-pathologising umbrella term for those sexual fantasies and patterns of arousal wherein the focus is mostly (or in some cases, solely) placed on our own embodiment (Serano, 2010, 2016). Bettcher (2014) has since expanded upon this concept of embodiment eroticism, providing numerous examples that illustrate the complexity of erotic content (which may involve our actual or imagined body, attraction toward real or imagined others, interactions between these bodies, additional elements or scenarios, plus the sexual meanings that we attribute to all of these things). Bettcher’s work demonstrates how autogynephilia theory reduces this rich content down to mere ‘attraction to’ people and objects. This is what allows Blanchard to misrepresent trans women’s embodiment fantasies as ‘misdirected heterosexual sex drives’ and ‘erotic target location errors’ (Bettcher, 2014).

In an earlier critique of autogynephilia (Serano, 2007, pp. 268-269), I facetiously coined the term ‘autophallophilia’ to describe the seemingly common fantasy that men sometimes have of receiving oral sex from a nondescript or faceless partner. My intention in forwarding the term was not to pathologise such fantasies, but rather to illustrate that cisgender men experience embodiment fantasies as well, even if they may not think of them in this way. Part of the

reason why these individuals (and most researchers who might study them) would be disinclined to view such fantasies in terms of ‘autophallophilia’ or MEFs is precisely because they are cisgender, and thus able to take their physical sex attributes for granted. Having a penis would likely be the unquestioned backdrop of most sexual fantasies that they experience, so its presence within the fantasy would not be seen as notable. In contrast, many transgender people (especially non- and pre-transition individuals) cannot take such attributes for granted, and are therefore likely to focus more on their own embodiment during both fantasies and real-life sexual experiences – eg, imagining themselves inhabiting the ‘right body’ or having the ‘appropriate parts’ (ie, those congruent with their identified gender). Critics of autogynephilia have long pointed out how MEFs and FEFs are an obvious coping mechanism to mitigate gender dysphoria, and the fact that trans women typically experience a sharp decrease in FEFs upon transitioning lends further credence to this notion (reviewed in Serano, 2010).

Another reason why many cisgender men are able to take their bodies for granted is because they are men. Gender theorists have chronicled how male bodies and perspectives tend to be viewed as neutral and the default standpoint in our culture, whereas female bodies and perspectives are marked and viewed as ‘other’ (Bem, 1993; de Beauvoir, 1989). Having been socialised in a heterosexual-male-centric culture, we all (to varying degrees) have internalised what feminists call ‘the male gaze’ – a mindset wherein men are viewed as sexual subjects who act upon their own desires, whereas women are viewed as passive sexual objects of other people’s desires (Fredrickson and Roberts, 1997; Mulvey, 1975). While the male gaze is most often discussed with regards to media representations, it can also inform our own self-conceptualisations and desires. For instance, it is relatively easy for many men (who regard themselves primarily as sexual subjects) to think about sex strictly in terms of whom they are ‘attracted to.’ But for many women, in addition to their own physical attractions toward other people, they will also be highly cognisant of the ways in which they are being sexually evaluated, appreciated, or objectified by other people (whether strangers, potential partners, or lovers), and this is bound to influence their subjectivity on sexual matters (Fredrickson and Roberts, 1997). Indeed, in their review of the research on sexual fantasies, Leitenberg and Henning (1995, p. 484) reported that, as a general rule, ‘Men’s fantasies are more active and focus more on the woman’s body and on what he wants to do to it, whereas women’s fantasies are more passive and focus more on men’s interest in their bodies’; Lehmillier (2018) found that this trend still largely holds true today. This disparity provides a relatively straightforward explanation for why FEFs are frequently experienced by women (whether cisgender or transgender, as both have to navigate the male gaze), whereas men are less likely to experience analogous MEFs.

Furthermore, given that we live in a culture where men are deemed sexual subjects and women objects of desire, it should not be surprising that female-specific clothing (and feminine gender expression more generally) is sometimes imbued with sexual meanings, whereas reciprocal items of masculine clothing and expression are typically viewed as utilitarian and devoid of sexual connotations (Serano, 2007). This helps explain why the phenomenon historically known as ‘transvestic fetishism’ (ie, sexual arousal experienced in response to crossdressing) has been found to be rather commonplace in trans female/feminine-spectrum individuals, but

is reported far less frequently in trans male/masculine-spectrum individuals. Unfortunately, this fairly obvious connection has remained obscured, as the researchers who studied the phenomenon classified it as a paraphilia and presumed that something must be inherently wrong with individuals who exhibited it. If, instead of studying this phenomenon as a psychopathology unto itself, these researchers had carried out controlled studies (à la Moser, 2009 and Veale et al., 2008) they would have found that many cisgender women also experience sexual arousal in response to wearing (or contemplating wearing) certain items of feminine clothing, at least in certain contexts. As further evidence that the concept of transvestic fetishism has been largely shaped by researchers' heteronormative and male-centric biases, psychologist Robert Stoller once argued that trans men cannot possibly experience transvestic fetishism on the basis that, 'Men's clothes have no erotic value whatsoever; these people have no clothing fetish' (Stoller, 1968, p. 195). Of course, some people *are* attracted to maleness and masculinity, and a subset of such individuals *do* experience sexual arousal in response to masculine clothing, as Bockting et al. (2009) found for many of their gay and bisexual male subjects.

A third factor that may influence embodiment fantasies is sexual orientation, albeit not in the way that Blanchard envisioned. Specifically, if an individual is attracted to femaleness and femininity in a more general sense (eg, they find such qualities erotic in their partners), then these same attributes might also be sexually salient with regards to their own embodiment, leading to more frequent or intense FEFs. (A similar correlation between attraction to maleness and masculinity, and MEFs, might also be expected.) Or to phrase this conversely: If an individual is *not* attracted to female or feminine attributes more generally, then they may be less likely to find FEFs arousing or compelling. This fairly simple explanation (which Blanchard never explored) is consistent with the correlations researchers have found between sexual orientation and embodiment fantasies, but without invoking direct causality.

While sexual orientation may partially explain the correlations Blanchard and others have reported, I do not believe it to be the primary factor. Rather, I argue that the frequent or intense FEFs experienced by many pre-transition 'non-classical' trans women stems largely from the fact that they passed through a 'crossdresser stage.'¹

In the essay 'Crossdressing: Demystifying Femininity and Rethinking Male Privilege' (Serano, 2007), I detailed the social forces that distinguish this transgender trajectory from others; here I will highlight the most pertinent points. First, it is well established that transgender people may experience the onset of gender dysphoria at various ages (Coleman et al., 2011). Individuals who become aware of their gender dysphoria early in childhood are likely to never fully identify with their birth-assigned gender – in fact, they often assert that they are, or should be, the 'other' (binary) gender from an early age. In contrast, individuals who become aware of their gender dysphoria later in childhood may have already come to accept their birth-assigned gender, as well as 'gender constancy' (the belief that one's gender can never change). As a result, these 'late-onset' trans people may initially self-conceptualise themselves as 'a boy who wants to be a girl' (or vice versa) for a period of time before fully embracing their gender-variant identities. This transitional stage can be especially perilous for trans female/feminine-

spectrum children, given that feminine boys are stigmatized to a far greater extent than masculine girls in our culture (Kane, 2006; Sandnabba and Ahlberg, 1999; Sullivan et al., 2018). This strict gender-policing essentially coerces these individuals into concealing or repressing any female/feminine inclinations they may have (if they are able to), particularly in public settings, and to only ever indulge them in private, either through daydreaming and fantasy, or secretive crossdressing – hence, the ‘crossdresser stage.’ Notably, there does not seem to be an analogous crossdresser stage for trans male/masculine individuals, presumably because their public explorations of gender will be tolerated to a greater degree (ie, others will perceive them as simply ‘tomboys’). Veale et al. (2010) have forwarded a similar model of crossdresser development.

During the pre-Internet era (when Blanchard conducted his research), there was little-to-no public awareness or accessible resources regarding transgender people, and trans children and teenagers were often left to their own devices to make sense of their situations. For trans individuals in the crossdresser stage, this meant grappling with one’s gender dysphoria in a milieu where (1) male-centrism ensures that girls’/women’s experiences and perspectives are ‘othered’ (and thus may seem ‘alien’ or ‘exotic’), (2) the male gaze encourages the general objectification of femaleness and femininity, and (3) these individuals may also be experiencing sexual attraction toward girls/women (independent of their gender dysphoria) for the first time. Given this set of circumstances, it is understandable why trans individuals in the crossdresser stage might experience FEFs (to varying degrees, and in some cases very intensely) in association with their early explorations of female gender identity and feminine gender expression.

As I have discussed throughout this section, embodiment fantasies may come in various forms. Some embodiment fantasies centre on the self: We are the same person that we are in everyday life, it is just that the focus of erotic attention is placed on our own body. Other embodiment fantasies revolve around us being or becoming someone else. Perhaps we share some qualities with this ‘someone else’ – eg they may be mostly like us, but only more attractive. In other cases, we might imagine ourselves as someone whom we believe (or were taught to believe) is entirely unlike us. If we cannot readily relate to this ‘someone else,’ we may draw heavily upon stereotypes. And in cases where we are not supposed to be (let alone *want* to be) this ‘someone else,’ these embodiment fantasies may feel forbidden and taboo. Obviously, FEFs and MEFs may fall into this ‘other’-embodiment fantasy category, albeit to varying degrees. Given that male experiences and perspectives are centred across Anglo-American culture, it might not be much of a stretch for a cisgender woman to imagine herself as a man in her fantasies. But because women’s experiences and perspectives are ‘othered,’ cisgender men might find FEFs to be especially exotic (what feminists and postcolonial theorists often call ‘exoticisation of the Other’). Furthermore, because femaleness/femininity are valued less than maleness/masculinity in our society, cisgender men may feel a sense of shame or ‘moral incongruence’ if they find FEFs particularly enjoyable or erotic, leading them to feel distressed about their own behaviors (Grubbs and Perry, 2019; Serano, 2020).

Some trans women's experiences with FEFs may overlap somewhat with those of cisgender men, particularly if they are in the crossdresser stage (wherein they are forced to publicly identify as male and repress any female/feminine inclinations). In other words, their FEFs during this phase may be predominantly 'other'-embodiment fantasies, characterised by exoticisation, stereotypes, and feelings of shame. In the case of cisgender men, this dynamic might never change. But as I chronicle in my aforementioned 'Crossdressing' essay, this dynamic does gradually change for trans women (as well as many crossdressers), as their gender dysphoria will lead them to explore and experiment with gender in real life, rather than exclusively within fantasies (Serano, 2007, 2010). Over time, femaleness and femininity will become 'demystified' to them, and they will begin to integrate their 'boy-mode' and 'girl-mode' into one whole person. They will stop feeling ashamed of their transgender, queer, female, and/or feminine identities, and may begin openly expressing them in public. As they do, they will come to relate to women's experiences and perspectives, especially once they begin moving through the world as women themselves. As this happens, FEFs may still occur on some level (as they do for cisgender women), but they will not be the sensationalised 'other'-embodiment fantasies of the past. Instead, they will largely be 'self'-embodiment fantasies, rooted in their own bodies and self-understandings. Blanchard was never able to adequately explain the sharp reduction in FEF prevalence that many trans women eventually experience – he actually proposed that it must be because these individuals have formed a 'pair-bond' with their female selves (reviewed and critiqued in Serano, 2010). But human sexuality is not a static thing, and trans people's self-conceptualisations, subjectivities, and desires may evolve over time.

Contemporary proponents of autogynephilia seem to believe that, just because Blanchard identified 'two subtypes' of trans women in a Canadian gender identity clinic in the 1980s, that these same two subtypes must still exist in the same form today, and presumably for perpetuity. This ignores the large body of research demonstrating that, while gender and sexual minorities exist in all cultures, their specific identities and behaviors are often shaped by local norms and social pressures, and that even within a given culture, different generational cohorts of LGBTQ+ people often display dramatically different self-understandings, life trajectories, and sexual histories (Hammack, 2005). In the thirty-plus years since Blanchard conducted his original research, there have been massive shifts in transgender awareness, visibility, legal recognition, and access to healthcare and resources. Today, 'late-onset' trans women are not necessarily forced into a crossdresser stage, as they can readily access information about transgender lives via the Internet or trans peers. Instead of engaging in secretive crossdressing and fantasy, many of these individuals come out as nonbinary, genderfluid, trans dykes, or queer women, and they often begin presenting femininely and/or socially transitioning as teenagers or young adults. And this lack of a secretive 'crossdresser stage' largely explains why these younger trans women experience far less FEFs than their counterparts from previous generations (Nuttbrock et al., 2011a, 2011b).

Sexologists today have moved away from viewing people who share the same sexual orientation, or experience similar sexual fantasies, as being the same 'type' of person, or suffering from the same 'paraphilia.' Embodiment fantasies come in many different permutations, and people may experience them for a variety of reasons. Like all sexual

fantasies, embodiment fantasies are not a permanent condition – they may appear, disappear, reappear, intensify, de-intensify, evolve, or shift over time. Any future research into embodiment fantasies should acknowledge the full breadth of this phenomenon, rather than misrepresenting them as some kind of transgender-specific psychopathology.

Autogynephilia promotes male-centrism, gender essentialism, and sexualises trans women

Thus far, I have reviewed the scientific case against autogynephilia, and forwarded an alternative ‘embodiment fantasy’ model that is consistent with all the available data and contemporary thinking on gender and sexual diversity. However, it is doubtful that the case I have made here (no matter how sound) will convince the theory’s staunchest defenders. In my experience, people who embrace autogynephilia often do so not because it best fits the evidence, but rather for ideological or sociological reasons. In this final section, I want to review these rationales, as they provide a better understanding of autogynephilia-related discourses.

Many people harbour gender-essentialist beliefs – for instance, that femininity and attraction to men is intrinsically female, and masculinity and attraction to women intrinsically male (Budge et al., 2018). When confronted with exceptions to this ‘rule,’ gender-essentialists’ go-to explanation is to presume these individuals must be ‘feminised men’ or ‘masculinised women’ – an assumption that invariably conflates gender expression with sexual orientation (Budge et al., 2018). Autogynephilia is a gender-essentialist theory, as it pathologises all transgender people for failing to conform to (cis)gender expectations. But of its two subtypes, Blanchard’s ‘homosexual’ group neatly fits a simplistic ‘feminised brain’ narrative, and as such, they receive relatively little consideration or scrutiny in his studies. In contrast, trans women who are not exclusively attracted to men, and/or not especially feminine as children, seemed to Blanchard to require some kind of extraordinary explanation, for which he invented autogynephilia. Tellingly, Bailey and Blanchard (2017) have recently expanded Blanchard’s typology to include *five* transgender subtypes, two of which are designed to explain the existence of ‘non-classical’ trans men (whose existence Blanchard initially dismissed, see Blanchard, 1989a). It seems both inefficient and scientifically dubious to invent new transgender subtypes (each with their own aetiology) any time a new demographic emerges that does not fit gender-essentialist stereotypes. It is far more parsimonious to acknowledge (as many contemporary researchers now do) that gender identity, gender expression, and sexual orientation can diverge from one another (and from one’s birth-assigned sex) within any given individual.

Speaking of stereotypes, according to autogynephilia lore, Blanchard ‘discovered’ that there are ‘two types’ of trans women, each with differing sexual motivations. In reality, these two types predate Blanchard’s work, as they are common stereotypes that have existed in the cisgender imagination for quite some time. In a review of a half-century’s worth of transgender-themed media depictions – the vast majority of which were produced without any knowledge or information about actual trans people or Blanchard’s theory – I identified two recurring trans woman stereotypes: the ‘deceiver’ and the ‘pathetic’ transsexual (Serano, 2007). In an independent analysis of laypeople’s reactions to trans women, Bettcher (2007) described these same stereotypes as ‘deceivers’ and ‘pretenders.’ These stereotypes differ from one another

primarily with regards to trans women's ability to 'pass' as cisgender women, and the motivations that are ascribed to each group reflect naive cisgender assumptions about why a 'man' might want to 'become' a woman. Perhaps because they are visibly feminine (which is also a common stereotype of gay men), 'deceivers' are typically presumed to be gay men who become women in order to sexually attract heterosexual men. The 'pathetic'/'pretender' stereotype is applied to trans women who do not 'pass' (and thus are incapable of 'deceiving' men), and the most common ulterior motive projected onto them is that they become women in order to fulfil some kind of bizarre sexual fantasy. These stereotypes share an obvious resemblance to Blanchard's 'homosexual' and 'autogynephile' subtypes, respectively. Given that these stereotypes have consistently appeared in the media since the 1960s (Serano, 2007, 2009), it seems likely that they may have influenced Blanchard's taxonomy. And perhaps the reason why people today still find autogynephilia theory compelling, despite the overwhelming evidence against it, is because it confirms their previously held stereotypes regarding trans women.

While the media (and cisgender laypeople's imaginations) consistently reproduce these two sexually motivated trans woman stereotypes, they also repeatedly overlook the existence of trans men. In rare cases where trans men *are* represented, it is usually not done in a sexually titillating manner (as it is with trans women), nor are trans men's transitions generally depicted as sexually motivated. It is hard not to draw parallels here with Stoller's claim that 'men's clothes have no erotic value whatsoever,' or Blanchard's insistence that 'autoandrophilia'/MEFs do not exist. I have argued that these discrepancies – ie, that trans women's motivations *must* be sexual, whereas trans men's *cannot possibly* be sexual – stem from the differing values that we (as a society) place on women versus men (Serano, 2007, 2009). In a male-centric society, the idea that someone might want to become a man seems somewhat understandable, whereas the reciprocal gender transition strikes most people as confounding. Thus, people tend to presume that trans women transition in order to obtain the one type of 'power' that women are commonly viewed as having: the ability to be objects of heterosexual male desire. In other words, the pervasive assumption that trans women transition for sexual reasons is rooted in the misogynistic belief that women, as a whole, have no worth beyond their ability to be sexualised (Serano, 2007, 2009).

Finally, in addition to male-centrism and gender essentialism, some people embrace autogynephilia theory (despite all the counter-evidence) because they are suspicious of, or ideologically opposed to, transgender people. Autogynephilia is a particularly useful tool in this regard, as it not only invalidates trans women's gender identities (by misrepresenting them as 'men' who suffer from psychopathologies), but because it *sexualises* them – it reduces trans women to their presumed sexual behaviors and motivations, to the exclusion of other characteristics (Serano, 2009). There is a large body of evidence demonstrating that women who are sexualised (often via 'slut-shaming') are viewed as less than human, are not taken seriously, are not treated with empathy, and face stigmatisation and social isolation as a result (American Psychological Association Task Force, 2007; Armstrong et al., 2014; Vrangalova et al., 2013). Similarly, other marginalised groups – including people of colour, immigrants, and LGBTQ+ communities – are also routinely depicted as hypersexual or sexually deviant, and

thus potential threats to non-minority women and children (Casares, 2018; Collins, 2000; Fejes, 2008; Frank, 2015; Stone, 2018).

Given that sexualisation is a tried-and-true tactic to dehumanise and socially exclude marginalised groups, it is unsurprising that social and religious conservatives – who routinely condemn women and LGBTQ+ people for their failure to conform to gender and sexual norms – increasingly invoke autogynephilia in their attempts to disparage transgender people (cf, Fitzgibbons et al., 2009). Feminists, on the other hand, have historically opposed male-centrism, heteronormativity, and gender essentialism. Given the long history of women being slut-shamed, and gender and sexual minorities (eg lesbians) being falsely accused of being sexual deviants and predators, it is hypocritical for any self-identified feminist to resort to these same tactics (via invoking Blanchard’s autogynephilia theory) in their attempts to exclude transgender people.

Note

1. To be clear, some people are lifelong crossdressers (for whom it is not a ‘stage’), and gender dysphoria is not the only reason why people crossdress. My analysis of the ‘crossdresser stage’ here specifically refers to eventually self-defined trans women, and is informed by many personal communications I have had with trans women about this particular stage of their lives.
